Employee Laptop Request Management System

Project Development Phase

Project Name	Employee Laptop Request Management System
Project Type	Individual Project
Document Date	12 September 2026
Platform	ServiceNow

1. Development Overview

The development phase describes the ServiceNow configuration used to implement the Employee Laptop Request Management System. The supplied project materials identify a custom request table, Record Producer, Business Rule, Flow Designer approval flow, email notifications, roles and ACLs.

2. Application Components

Component	Purpose	Evidence required for final verification
Scoped application	Hosts the application components.	Application details page and scope.
Laptop Request Form table	Stores submitted laptop requests.	Table definition and field list.
Record Producer	Provides the employee submission form.	Record Producer configuration and live form.
Business Rule	Checks one request per requester per calendar year before insert.	Business Rule script and duplicate test.
Flow Designer	Sets Pending Approval, requests manager approval and handles outcomes.	Flow diagram and execution details.
sysapproval_approver	Stores approval activity.	Approval record linked to a request.
Notifications	Communicates approval requests and outcomes.	Notification configuration and received email.
Roles and ACLs	Restricts create/read/write operations.	Role records and ACL evaluation.

3. Request Processing Logic

The intended processing sequence is: employee opens the Record Producer; enters requester, email, manager, request type, reason and short description; submits the form; a before-insert Business Rule checks whether the requester already has a request in the current calendar year; valid records proceed to Flow Designer; the flow sets Pending Approval and asks the referenced manager for approval; the decision updates status to Approved or Rejected and triggers the configured notification.

4. Annual Duplicate Validation

The supplied development notes describe a before-insert Business Rule on the Laptop Request Form table. The query checks the requester and a date range bounded by the beginning and end of the current year. If a matching record exists, the rule displays an error and aborts the insert. The exact field names and implementation script must be checked in the live instance.

5. Flow Designer Approval

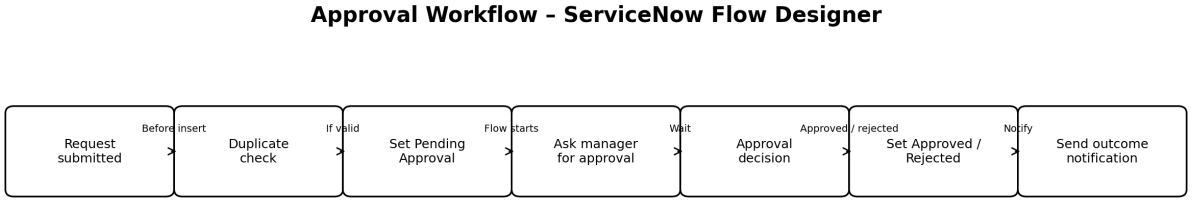

Figure 1. Logical approval flow derived from the supplied configuration notes.

6. Role and ACL Design

Role / control	Intended permission	Validation action
it_employee	Create, read and write permitted request records.	Test create/read/write using an employee account.
it_manager	Read/view request records; no general create or modify access.	Test read and attempt create/write using a manager account.
Table-level ACL	Protect record operations at table level.	Review none/create/read/write ACLs and conditions.
Groups	Assign roles to the appropriate IT employee and IT manager groups.	Check group membership and inherited roles.

7. Testing and Deployment Activities

The source development report lists functional, approval, notification, security and end-to-end scenarios as passed. However, the ZIP does not contain corresponding live-instance screenshots, execution logs or signed UAT evidence. Therefore, this revised report records these as results stated in the original project materials, with independent evidence still required.

8. Deployment Procedure

Recommended deployment sequence: confirm the correct application scope; complete and review the update set; preview it; resolve conflicts; commit it; export the update set XML if required; import it into the target instance; validate the application, table, Record Producer, Business Rule, Flow Designer, roles, ACLs and notifications.

> Note: No live ServiceNow screenshots have been fabricated. The included diagrams are logical illustrations. Insert genuine screenshots from the configured instance in the evidence section before final academic submission.
