Employee Laptop Request Management System

Final Project Documentation

Project Name	Employee Laptop Request Management System
Project Type	Individual Project
Document Date	12 September 2026
Platform	ServiceNow

1. Executive Summary

The Employee Laptop Request Management System is an individual project developed on ServiceNow to standardize employee laptop requests. It uses a Record Producer, a custom request table, a Business Rule for annual duplicate prevention, Flow Designer for manager approval, notifications and role-based access controls.

2. Project Objectives

The objectives are to centralize laptop request submission; capture complete and consistent request information; prevent duplicate requests by the same requester within a calendar year; route requests to the appropriate manager; maintain Pending Approval, Approved and Rejected states; notify relevant users; and restrict access according to configured roles and ACLs.

3. Scope

Included	Not claimed / outside verified scope
Record Producer request submission; custom request table; request classification; annual duplicate policy; manager approval; status updates; email notifications; roles and ACLs; update-set deployment procedure.	Hardware procurement, physical inventory, laptop allocation/return tracking, enterprise integrations, production-scale performance benchmarks and signed external UAT are not evidenced in the supplied source files.

4. Solution Architecture

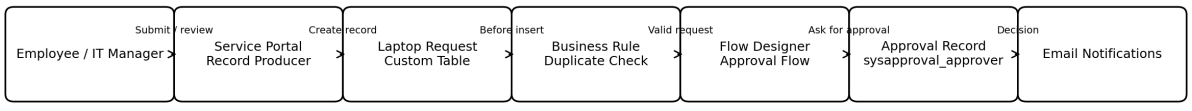

Figure 1. ServiceNow logical architecture.

5. Functional Overview

An employee submits a request through the Service Portal Record Producer. The request information is stored in the custom Laptop Request Form table. A before-insert Business Rule checks for a request by the same requester in the current calendar year. A valid request is processed by Flow Designer, which sets Pending Approval and asks the referenced manager for approval. The flow then updates the status to Approved or Rejected and sends the configured outcome notification.

6. Roles and Responsibilities

Role	Responsibilities
Employee / requester	Submit complete laptop request information and review status/outcome.
IT Manager	Review assigned approval and approve or reject the request.
IT Employee	Manage permitted request records according to ACLs.
ServiceNow administrator	Maintain application configuration, security, workflow, notifications and deployment.

7. User Guide

7.1 Employee / Requester

1. Open the ServiceNow Service Portal. 2. Select the Laptop Request Record Producer. 3. Verify requester and employee email. 4. Enter short description, manager, request type and reason. 5. Submit the request. 6. Review the request status and any notification. If a request already exists for the same requester in the current calendar year, the duplicate rule is intended to block a second submission.

7.2 IT Manager

1. Open the approval request received through ServiceNow. 2. Review the employee and laptop requirement details. 3. Approve or reject the request. 4. Confirm the approval outcome is reflected in the request status. The requester should receive the configured notification.

7.3 Administrator

Maintain roles, groups and ACLs; review the Business Rule and Flow Designer configuration; verify notification recipients and conditions; review update-set contents; preview and commit only the correct project update set; validate the target instance after deployment.

8. Testing Summary

The original development documentation reports successful scenarios for request creation, duplicate prevention, manager approval, status outcome, notifications and access control. The revised Testing Phase document distinguishes reported results from independently evidenced results because the ZIP did not include live execution screenshots or logs.

9. Deployment and Handover

A correct deployment package should contain the scoped application and all required table, field, Record Producer, Business Rule, Flow Designer, notification, role, group and ACL changes. The supplied XML file is not suitable as the final handover artifact: it identifies an update set called HR onboarding application, is marked Global, and contains a single DELETE action for a sys_app record. Export a fresh update set from the correct application scope and inspect its contents before submission.

10. Limitations and Future Enhancements

Current documented scope	Possible future enhancement
Basic / Advance request classification	Add configurable laptop models and technical specifications.
Manager approval and status tracking	Add multi-level approval for high-value requests.
Annual duplicate validation	Make the policy configurable by department or request category.
Email notifications	Add in-platform notifications and reminder/escalation rules.
Role-based access	Add detailed field-level access and audit reporting.

11. Conclusion

The project defines a centralized ServiceNow workflow for employee laptop requests and documents the principal configuration, requirements, design, planning and testing approach. Before final submission, attach genuine instance screenshots, complete live retesting, correct the update-set export and verify all repository links. The project is an individual project; no team-member details apply.

Note: Project date retained from the original documentation: 12 September 2026. The separate demonstration video is intentionally excluded from this documentation pack as requested.
